Molecular Underpinning of Vesicant Chemical Injury and MCM Development

Mohammad Athar, Ph. D.

Department of Dermatology

UAB THE UNIVERSITY OF ALABAMA AT BIRMINGHAM

Introduction

- **A large number of highly toxic chemicals which are used in chemical warfare or for industrial purposes pose significant threat to the environment and human health if exposed accidently or during the terrorist attack (**Homeland Security identified 200 chemicals segregated as Toxidrome**)**
- **Arsenicals are one group of such chemicals in the category called vesicants, which were developed and weaponized during world wars I and II**
- **Of these, Lewisite (2-chlorovinyl-dichloroarsine) is the best-known rapid action chemical weapon given the nick name 'Dew of Death'**

Li et al. Ann N Y Acad Sci. 2016, 1378(1):143-157.

- Arsenicals cause severe painful inflammation in the skin, eye and lungs
- Their cutaneous exposure also causes severe systemic injury often leading to lethality in humans. These include acute kidney damage, lung, liver, immune and neural injury
- The molecular pathogenesis of lesions caused by these chemicals remains largely undefined. Therefore, our focus is on unraveling the molecular pathogenesis of arsenicals in the skin, lung and kidney following their cutaneous exposure
- To develop mechanism-based effective counter-measures which can effectively block tissue damage, morbidity and lethality in animal models

U.S. Accuses Russia of Using Chemical Weapons in Ukraine

The State Department said Russia had used chloropicrin, a poison gas widely used during World War I, against Ukrainian forces, an act that would violate a global ban signed by Moscow. Nicole Tung for The New York Times, May 2, 2024

Needs for Developing Medical Countermeasures (MCMs) for Toxic Agents

- Suitable animal models which can faithfully recapitulate the human pathogenesis of toxic chemical (more than one model) & identifying a surrogate chemical that can be used in the laboratory safety conditions
- Defined molecular pathogenesis of lesions caused by exposure to these chemicals with druggable molecular target(s)
- Defined molecular toxidrome (identifying common targets)
- Availability drugs that can be repurposed or novel small molecules with IP rights

iii. Fyrlklovern Scandinavia

4-PBA+taurursodiol

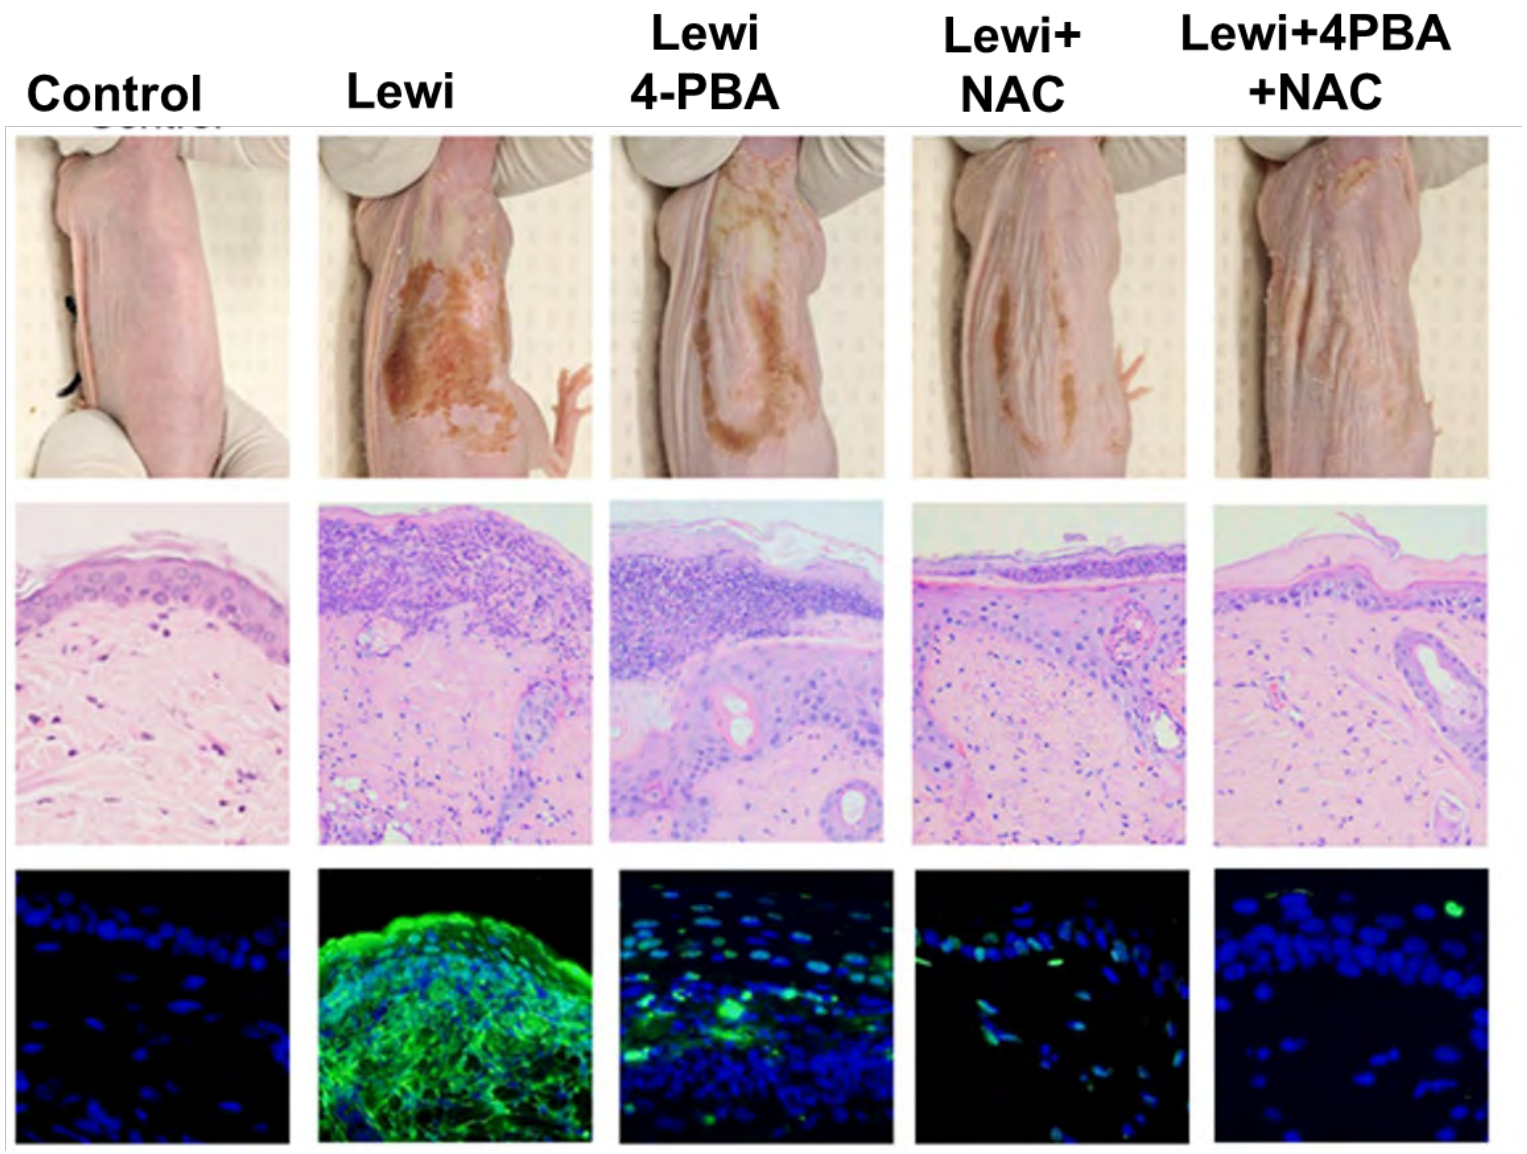
(FDA approved for Amyotrophic Lateral Sclerosis 09/2022)

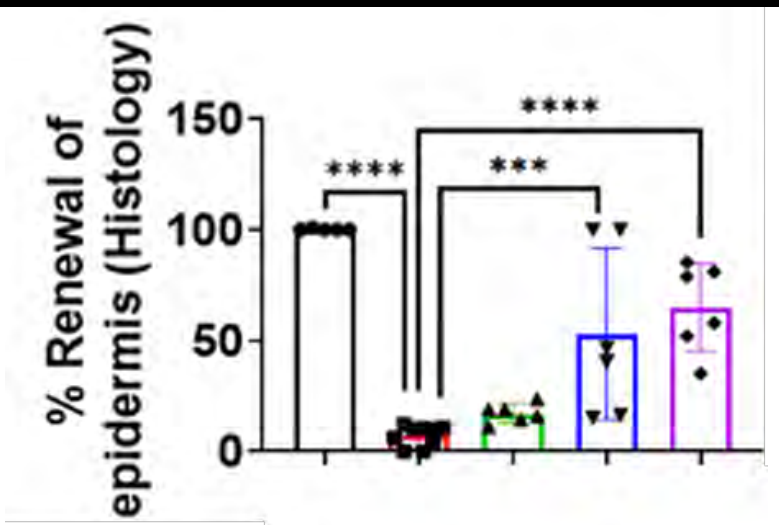
N-acetyl Cysteine (NAC)

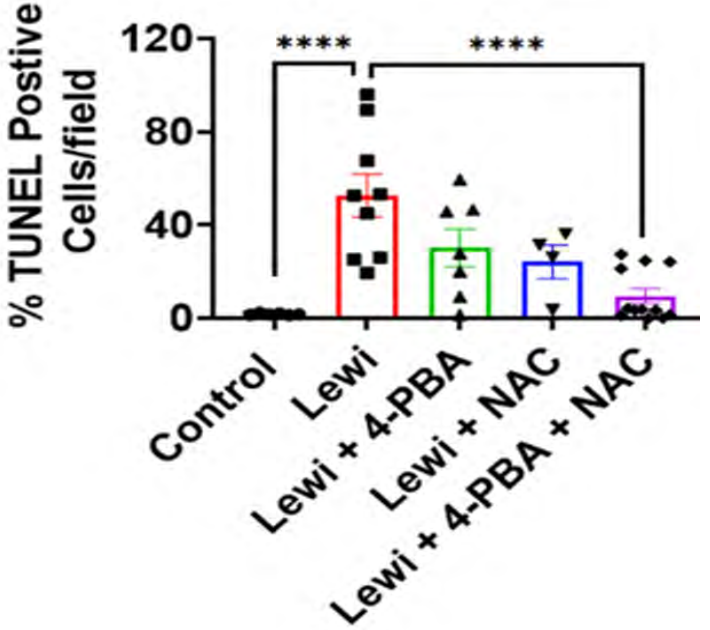
(FDA approved for overdose toxicity of Acetaminophen on January 23, 2004)

Marketed by: Cumberland Pharma

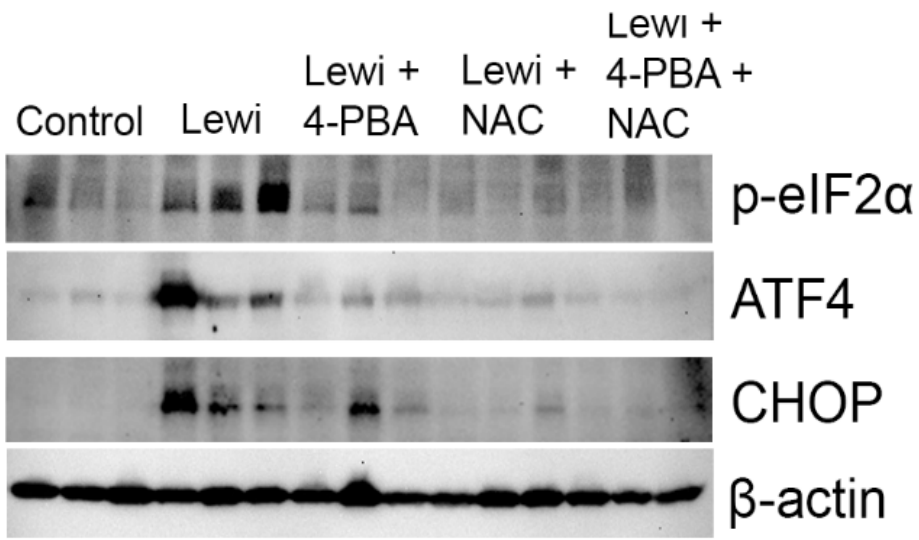
Combination of 4-PBA+NAC is Highly Effective in Attenuating Arsenical-induced Cutaneous Injury in Mice

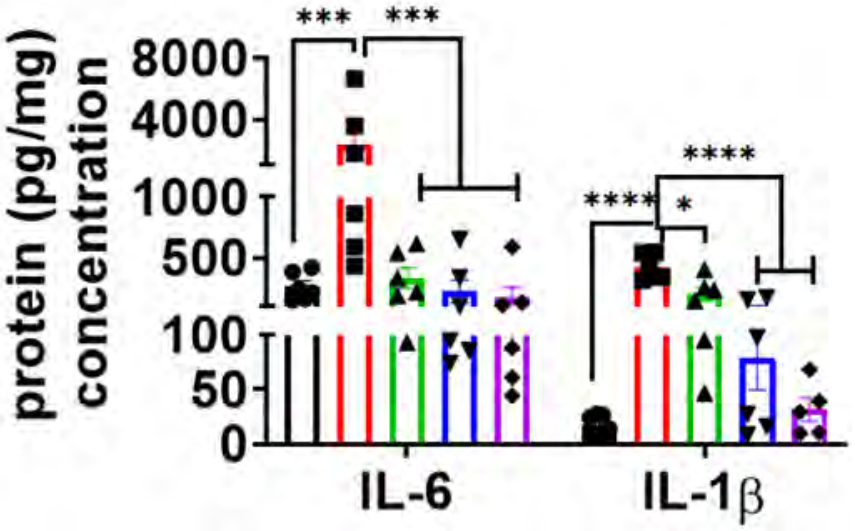


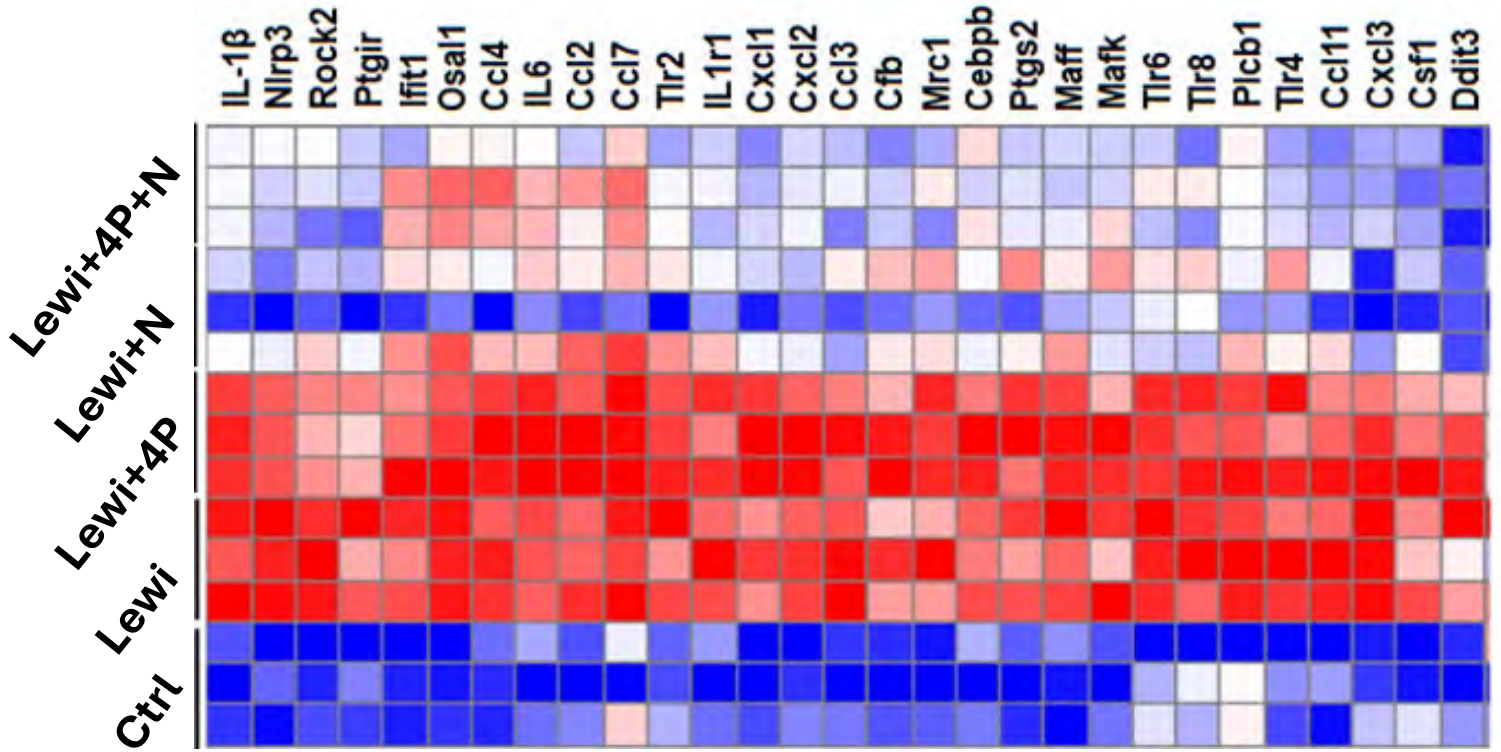




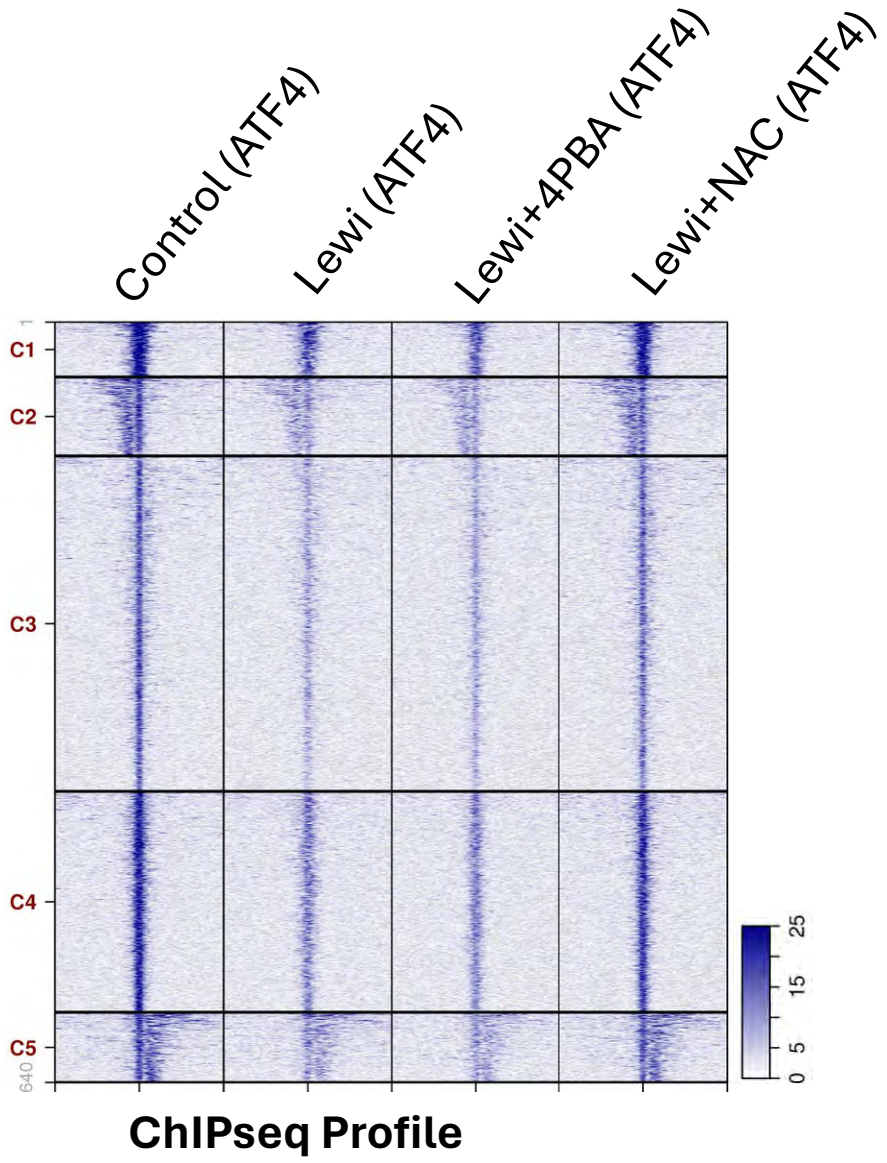
Combination of 4-PBA+NAC Reverses Lewisite-induced Inflammatory Phenotype in Mouse Skin

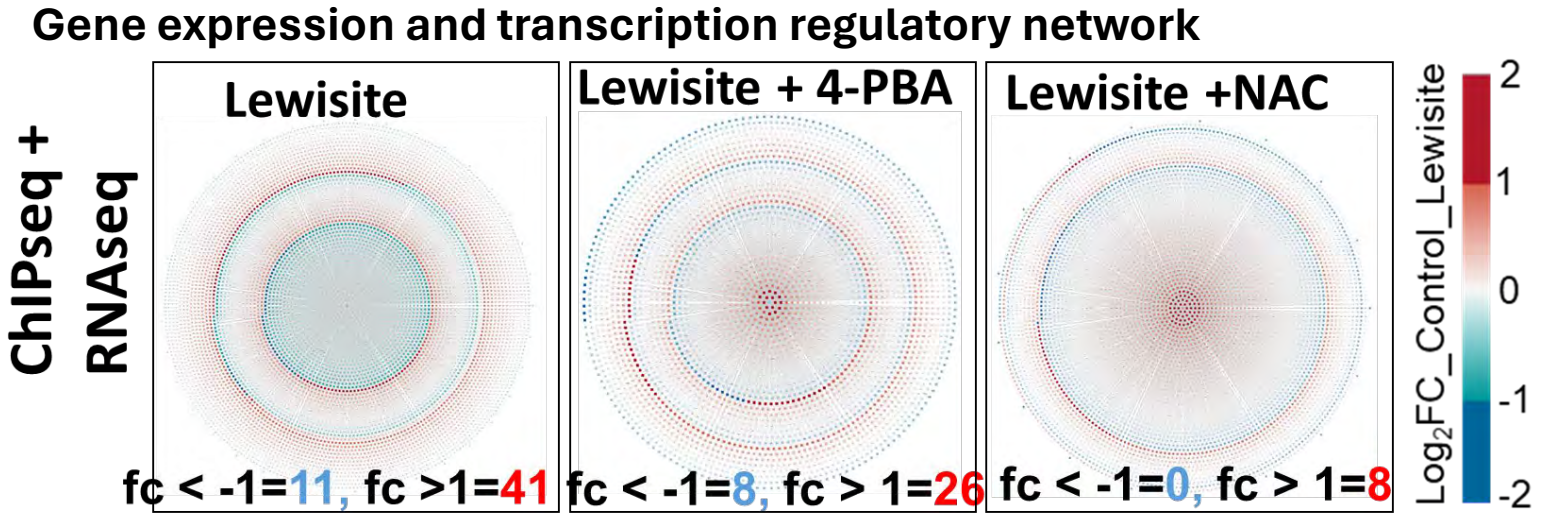


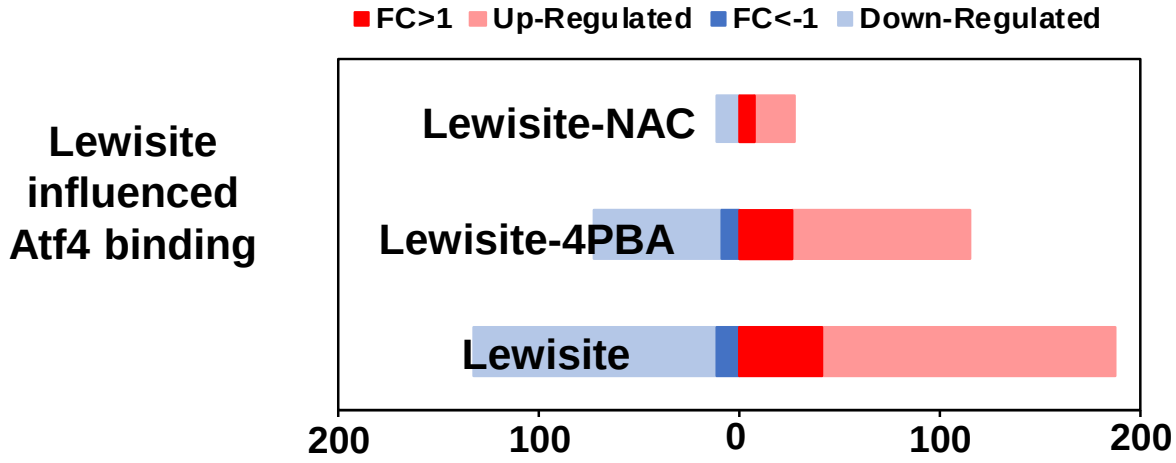




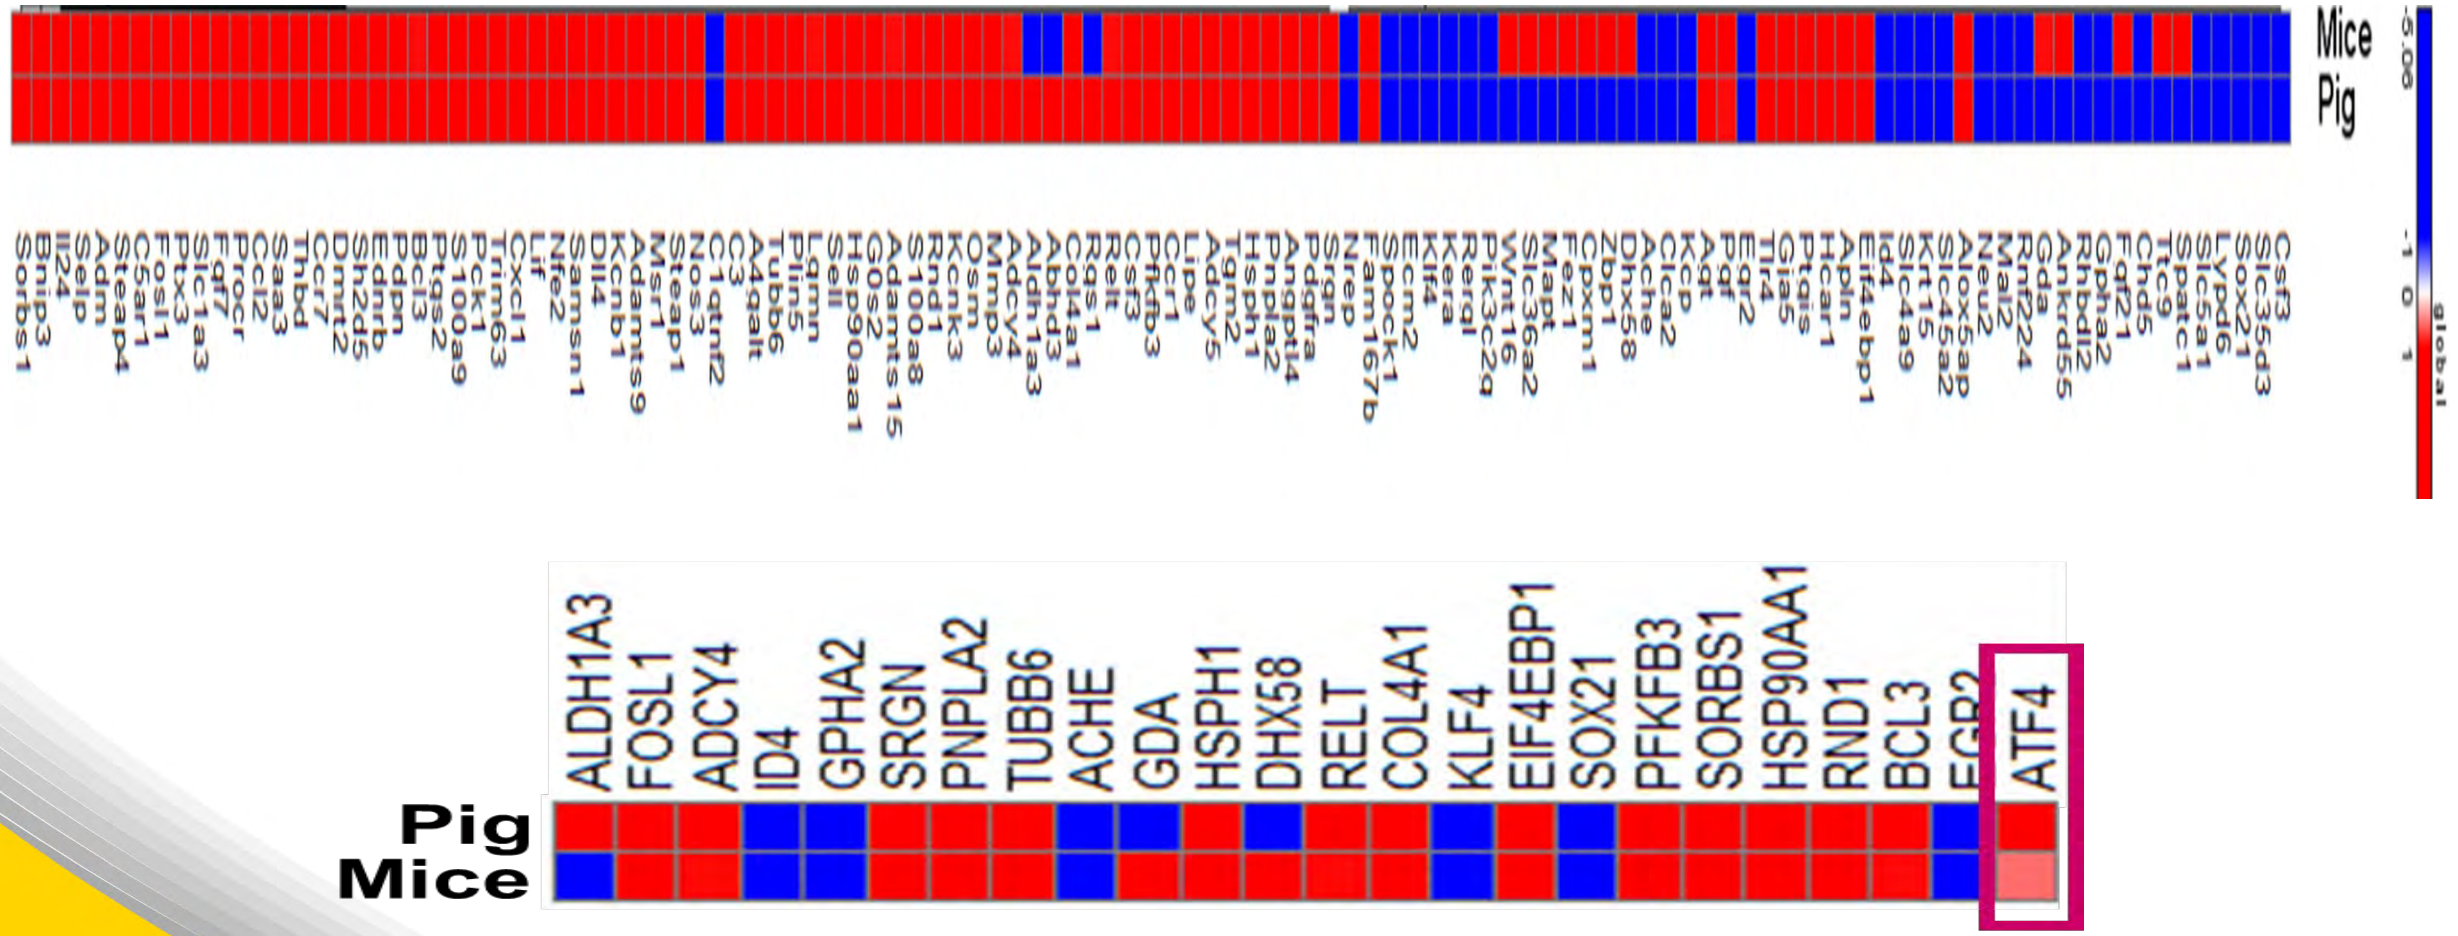
Combination of 4-PBA+NAC Reverses Lewisite-induced Alterations in Genomic Occupancy of ATF4 in Mouse Skin



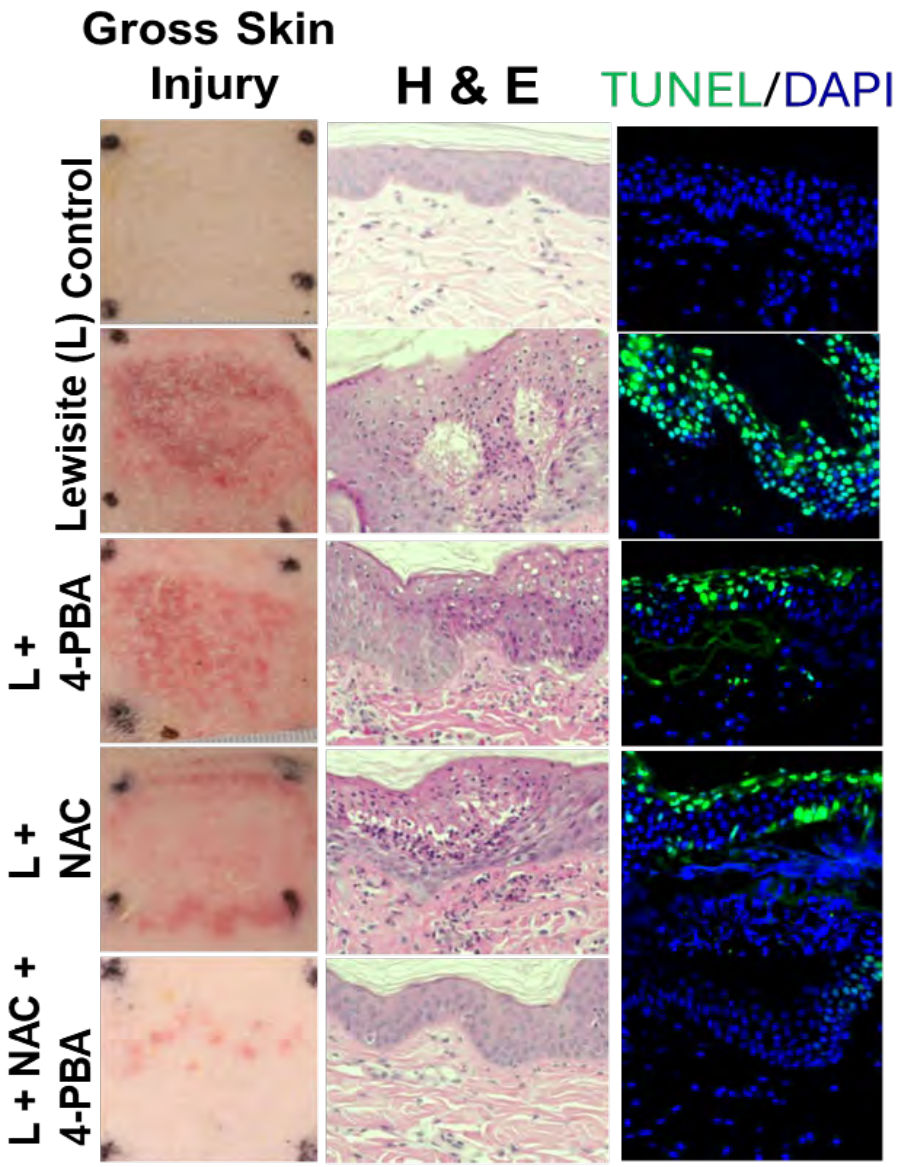


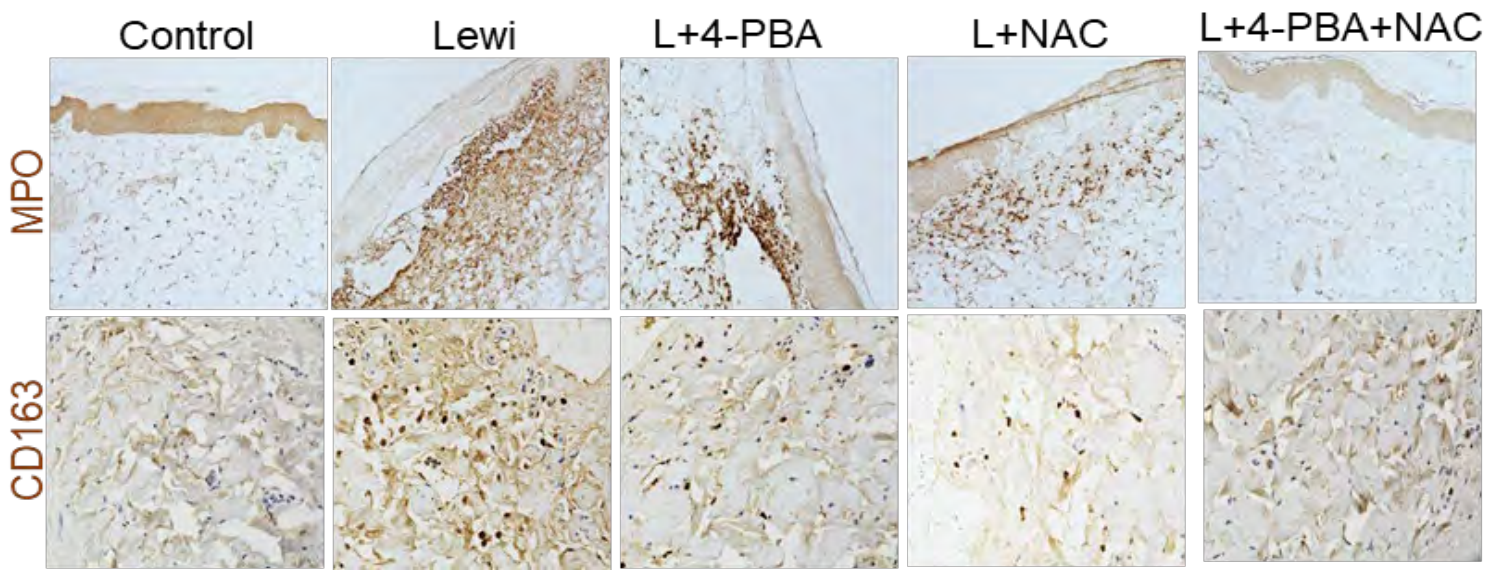


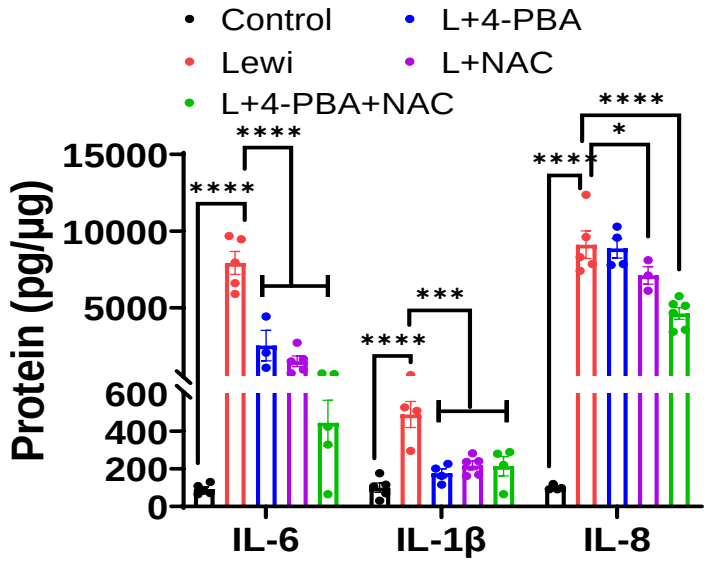
Expression of Common Genes (RNASeq) in Mouse and Porcine Models

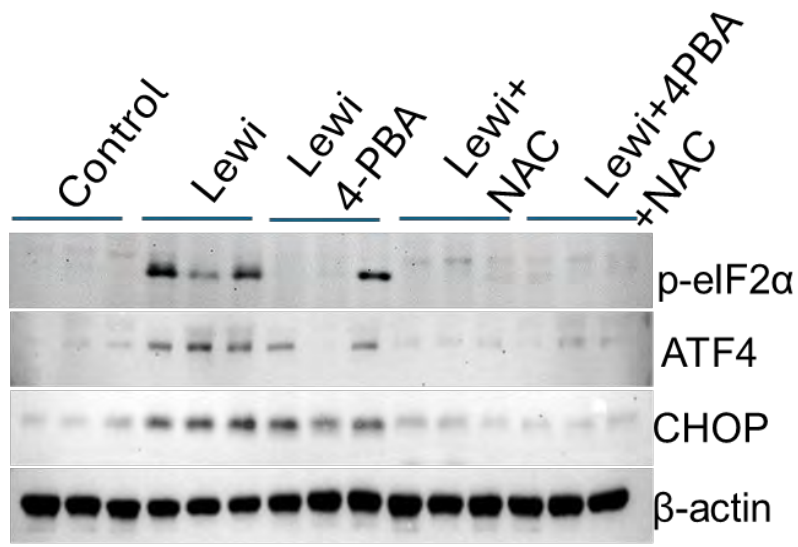


Combination of 4-PBA+NAC is Highly Effective in Attenuating Arsenical-induced Cutaneous Injury in Minipig









Conclusions

- 4-PBA in combination with NAC provides a highly effective MCM against Lewisite and acts by attenuating ER stress and protein translation.

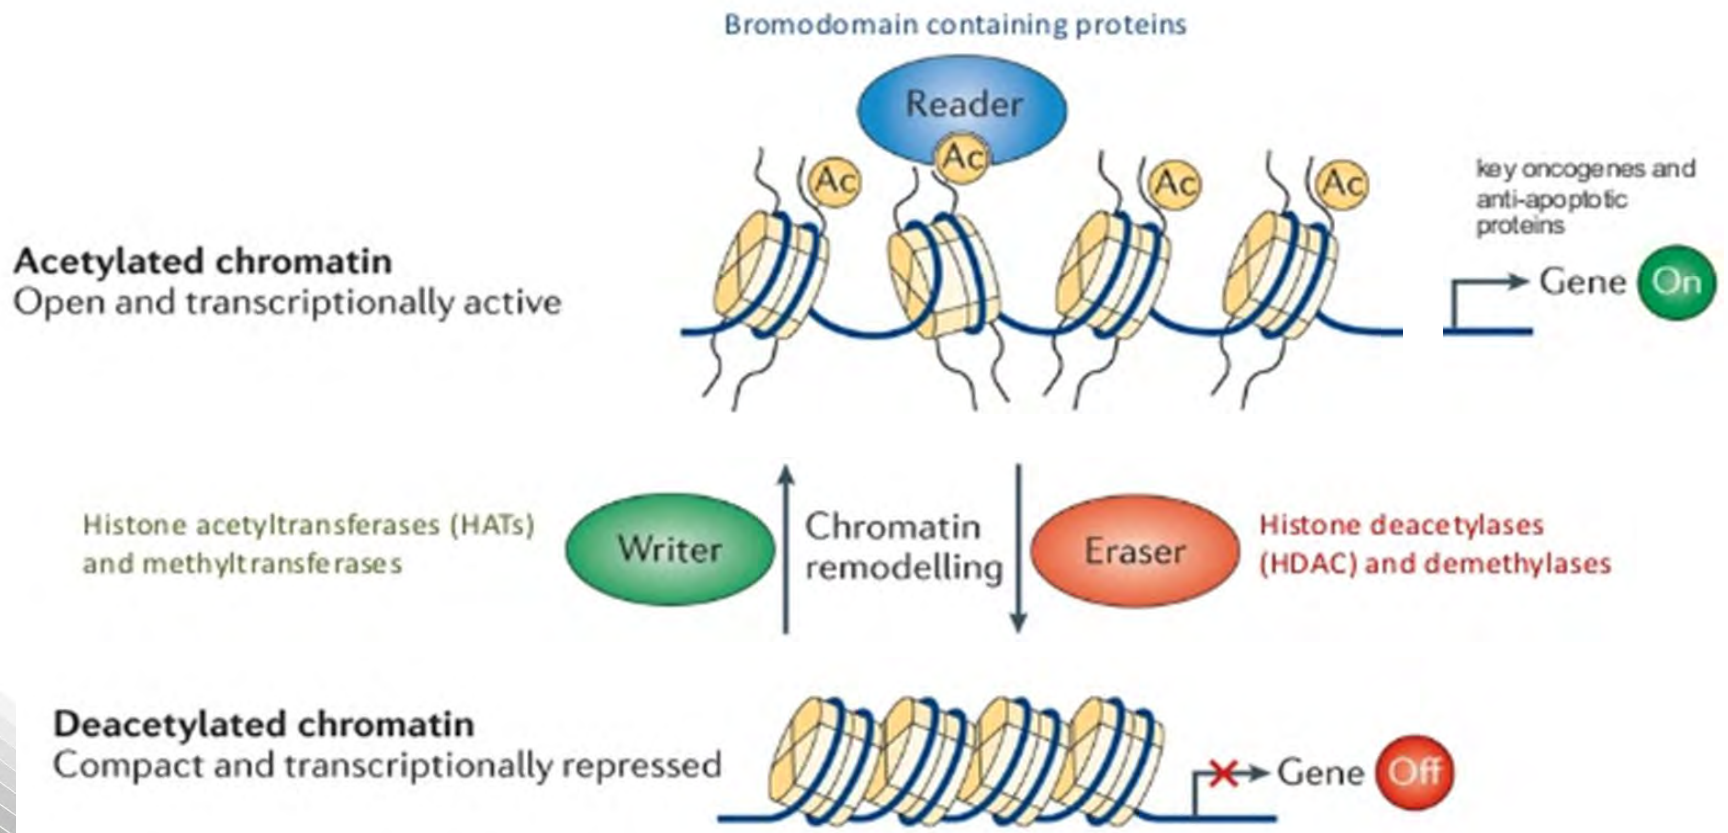
- This treatment is equally effective against other arsenicals induced vesicant injury

Epigenetic Mechanisms Regulating Blistering, Nociception and Tissue Disruption

Hypothesis

The unifying hypothesis is to uncover the role histone hyper-acetylation-dependent epigenetic regulation of multiple signaling pathways, which orchestrate the robust inflammatory and tissue damaging responses induced by arsenicals. The epigenetic reader bromodomain 4 (BRD4) as a novel, potent therapeutic target for mitigating arsenicals-induced tissue injury will be investigated.

Targeting Bromodomains: Epigenetic Readers of Lysine Acetylation



Transcription of Genes in Inflammation, Tissue Damage/ Remodeling

Nature Reviews Molecular Cell Biology 16, 258–264 (2015)

BET Bromodomain Therapeutic Activity

- Bromodomain family of proteins are involved in reading of acetylated lysine on histones DNA and facilitate the transcriptional regulation of various inflammatory and oncogenes.

- Bromodomain inhibition leads to gene expression changes that may affect pathological conditions of various inflammatory diseases.

Summary

- Established murine and porcine models of skin exposures to single high dose of vesicants that recapitulate human pathobiology of cutaneous and systemic injury
- Developed molecular toxidrome of blistering agents with an objective to develop single MCM for multiple toxic chemicals
- Identified additional multiple druggable molecular targets and assessed their potential utility in MCM development

Summary (continued.)

- Two distinct MCMs have advanced with remarkable efficacy in two animal models against lewisite and other vesicants with defined molecular targets and mechanisms of action
- Developed impressive pipeline of MCMs which are at different stages of preclinical development and include novel (with IP rights) and repurposed drugs

Conclusion

Our translational approach is “Mechanism to Clinic”. In this regard, we are also identifying surrogate disease with similar molecular pathogenesis for FDA approval and stock piling.
